vestibular tolerance, nausea developed within 2—5 min; for second-degree tolerance, within 5—10 min; for first-degree tolerance, within 10—15 min, and for the maximum-tolerance group, within 15—20 min. With the head tilted forward, nausea occurs 1—4 min later than with the head tilted to the side. The experiments showed that the higher the tolerance, the later the symptoms developed. Pulse rate was insignificantly affected. In those with normal vestibular tolerance, recovery took place within 5—20 min after the experiments. In those with a low (fourth-degree) vestibular tolerance, recovery took place after 40—60 min. The results of the vestibular tolerance tests showed the percentages of those who developed sickness — on Khilov's swing, 4.9%; in ten repetitions of Voyachek's otolithic tests, 9.8%; during continuous cumulation of Coriolis accelerations within two minutes, 12.6%. It was concluded that the method of continuous cumulation of Coriolis acceleration can reveal latent forms of vestibular tolerance better than other methods. Thus, the continuous cumulation of Coriolis accelerations is the most effective method for studying vestibular tolerance and selecting flight candidates. Orig. art. has: [sc] 1 figure.

TITLE: Vestibular selection using a method of continuous Coriolis acceleration cumulation

SOURCE: Voyenno-meditsinskiy zhurnal, no. 9, 1966, 59-62

TOPIC TAGS: vestibular analyzer, vestibular training, vestibular function, cosmonaut selection, space physiology, CORIOLIS FORCE, VESTIBULAR DISTURBANCE

ABSTRACT: The article contains data characterizing the effectiveness of the selection method based on continuous cumulation of Coriolis accelerations. The value of this method is that it is well controlled. Experiments were conducted on pilots. Vestibular reaction was based on illusions of rocking, hot flashes, a tendency to perspire, paleness, and nausea. Pulse rate and the temperature of the head and hands were also monitored. Results showed that vestibular-sensory and autonomic reactions during cumulation of Coriolis accelerations developed progressively, beginning with a rocking sensation, and ending in nausea, sometimes with vomiting. Nausea developed within two minutes for people with fourth (least)-degree vestibular tolerance during Coriolis cumulation in a head-tilted-forward position; in those with third-degree

Abstract : Generally, during chronic tonsilitis, in impression specimens of the tonsillar surface, granulocytes predominate and the quantity of segmentonuclear neutrophils increases. Lymphocytes are encountered in various quantities, sometimes making up nearly half of the computed cells. Immature forms of lymphocytes are few; lymphoblasts are unitary. The quantity

dilute solutions (toluene, m-xylene, ethylbenzene and cyclohexanol) in the cooling of the solutions, and 3) by precipitating the polycarbonates with methanol from dilute solutions in methylene chloride. Figs. 1-12 show the structure. In the two first-mentioned ways of production, polycarbonates with a strongly asymmetrical, fibrous structure are obtained. This structure is due to a linking of the primarily formed structure of the chain packets, and undergoes no morphological change no matter whether the chains of the packets are crystalline or amorphous. This is in agreement with the findings of the author in a previous paper (Ref. 1), and apparently explains the specific character of the mechanical properties of these polymers, especially the high impact strength; the elasticity may be ascribed to the fibers of the polycarbonates. On precipitating with methanol, a spherical structure that is characteristic of colloidal systems occurs. This structure is unstable, and in the case of heating the fiber structure typical of polycarbonates is formed. There are 12 figures and 7 references: 4 Soviet and 3 German.

PERIODICAL: Vysokomolekulyarnyye soyedineniya, 1960, Vol. 2, No. 6,
pp. 931-936

TEXT: Electron microscopic examinations were made of the secondary structure of 2,2-bis-(4'-oxyphenyl)-propane polycarbonate. Basing on the data of the method of experimenting and the results obtained, the authors discuss the concept of flexible and rigid molecule chains and, among other things, they indicate that differentiation should be made between two types of links of polymer chains, i.e. the chemical and the kinetic chain link of polymer molecule chains. The examinations were made with a Y3M-100 (UEM-100) electron microscope. High-molecular polycarbonate fractions were used (molecular weight 83000 and 230000) whose secondary structure was produced in three ways: 1) by evaporating the solvent from very dilute polycarbonate solutions (chlorobenzene, benzene), 2) by separation from

by Fig. 2, polymers synthesized in a heterogeneous medium have an anomalous distribution of molecular weights. The thermomechanical properties and the transition temperatures were studied for fractions with molecular weights of from 5,000 to 220,000 (Figs. 3-5, Table). The low-molecular fractions showed no softening point but passed directly from the vitreous into the viscous state. After crystallization, their transition temperature was 70°C higher. In polymers with higher molecular weight and a polymerization degree of 40, the chains became flexible on heating. These products became highly elastic. A further temperature increase, however, led to hardening as a result of crystallization (Fig. 6). In low-molecular polymers it occurred at lower temperatures than in high-molecular ones. The polymers having the highest molecular weight showed the typical behavior of amorphous polymers. According to their molecular weight, polycarbonates have the properties of both crystallizing and amorphous polymers. As to the flexibility of the chains, they hold an intermediate position between polyisobutylene and polyvinyl chloride, although polycarbonate products are characterized by high strength and hardness. This contradiction is explained by a specific steric structure of the large polycarbonate

Klimek W., Makarucha Z. Spectrographic Determination of Alloying

Constituent's In Steel.

"Spektrograficzne oznaczanie zawartości składników stopowych w stali". (Prace Inst. Metallurgii No. 2), Katowice, 1952, PWT, 16.5 pp., 23 figs., 8 tabs.

A method was worked out of spectrographic determination of Mn, Si, Cr, Ni, Mo and V in low alloy and carbon steels. It is based on the use of a Soviet made quartz spectrograph of mean dispersion. Spectra were excited by a simple condensed spark circuit. A set of spectrographic standards were prepared in a laboratory arc furnace. The flat surface standards in conjunction with a 4.5 mm dia. carbon counter electrode were used throughout the experiments. Several lines pairs cited by different authors have been used and the results discussed. The most suitable lines chosen for routine examination are given in a corresponding table. In the case of vanadium, not a single line yet found in literature could be accepted. The best results were obtained with a pair chosen by the authors (Fe 3052,233/V 31'0,703). The authors point out some causes of errors which arise from low dispersion, Pre-sparking of 60 seconds, followed by an interruption interval of 15 sec. and a 15 sec. exposure gave more accurate results than if exposure follows immediately on pre-sparking. Errors resulting in variations of size of specimens analysed were examined; no serious errors were found so long as the weight of the sample was not less than 30-50 g.

ABSTRACT: Single channel, special purpose 1A01-1 and 1A01-2 type optimizers designed for finding the extremum of a function of one variable are described. Different versions of these two types of optimizers have been built for use in various industrial applications. The optimizers are shown in figures 1 and 2.

to the trailer with a turning mechanism that regulates their turn to the correct angle in rotation to the coupling. The trailer wheels then track with the truck tractor's. To increase the average speed of movement over earth roads and roadless terrain, the drive to the powered trailer should be adjusted so that the train's rate of movement is approximately 30-40% the maximum speed of the truck tractor alone. There are 9 figures and 4 tables.

Some results of studies...

powered trailers; the traction properties of trains with normal or with powered trailers; the effects of power distribution between the truck tractor and the trailer on the train's total tractive force; comparative fuel consumption in trains operating with normal or with powered trailers. The roadability tests were carried out over sand and over snow, while the other tests were held over a concrete road, on meadow ground, on sand and over plowed ground. It was found that the use of powered-trailers greatly increases the train's tractive force and roadability. When the powered axles are engaged, the tractive force increases more than does the train's coupling weight. Over rough terrain, a train with powered trailers is more economical and has a higher speed than a train with normal trailers. Disparity in the peripheral speed of the wheels on the truck tractor and the trailer causes the wheels to slip and slide, thereby reducing the train's tractive force. These losses vary directly with the kinematic disparity and the wheels/ground coupling factor. On curves a further fall in tractive force occurs if the trailer wheels follow a track other than that described by the truck tractor. This can be avoided by fitting steerable wheels

TITLE: Some results of studies of automobile trains with
powered trailers

PERIODICAL: Avtomobil'naya promyshlennost', no. 11, 1960, 13-17

TEXT: The article gives the results of a study of a powered motor vehicle train with mechanical power transmission to a single-axle trailer and a train with electrical power transmission to a twin-axle trailer. In the first instance a ГАЗ-63 (GAZ-63) truck was used, specially fitted with a ЗИЛ-151 (ZIL-151) distribution box from which torque was applied via a Cardan shaft to the trailer's axle. In the second instance a ZIL-151 truck with a ЯАЗ-204B (YaAZ-204V) motor and trolley bus electrical equipment (electric motor, shunt rheostats, controllers, etc.) was used. Tests were made to determine: The roadability of trains with normal or with

TITLE: Designing the push-pull magnetic amplifier

SOURCE: IVUZ. Energetika, no. 10, 1966, 25-30

TOPIC TAGS: magnetic amplifier, electric motor

ABSTRACT: In automatic control systems of DC motors with pulsed measuring devices which incorporate a monovibrator the pulse signals of the arms of the monovibrators must be converted to DC signals. This may be accomplished with the aid of the push-pull magnetic amplifier (MA) described by the authors. The MA consists of two reactive resistors, two ohmic resistors, two load resistors, one reactive and one ohmic resistor of the smoothing choke at the output of MA. The push-pull MA is constructed from two single-cycle MAs, each connected to one arm of the monovibrator. The design and calculation of MA are based on the similarity of the characteristics of MA fabricated from the same magnetic materials but differing in volume of steel, supply voltage, on taking the following factors into account: maximum and minimum voltages at the output of the
